

Greedy Algorithms

Interval scheduling Problem

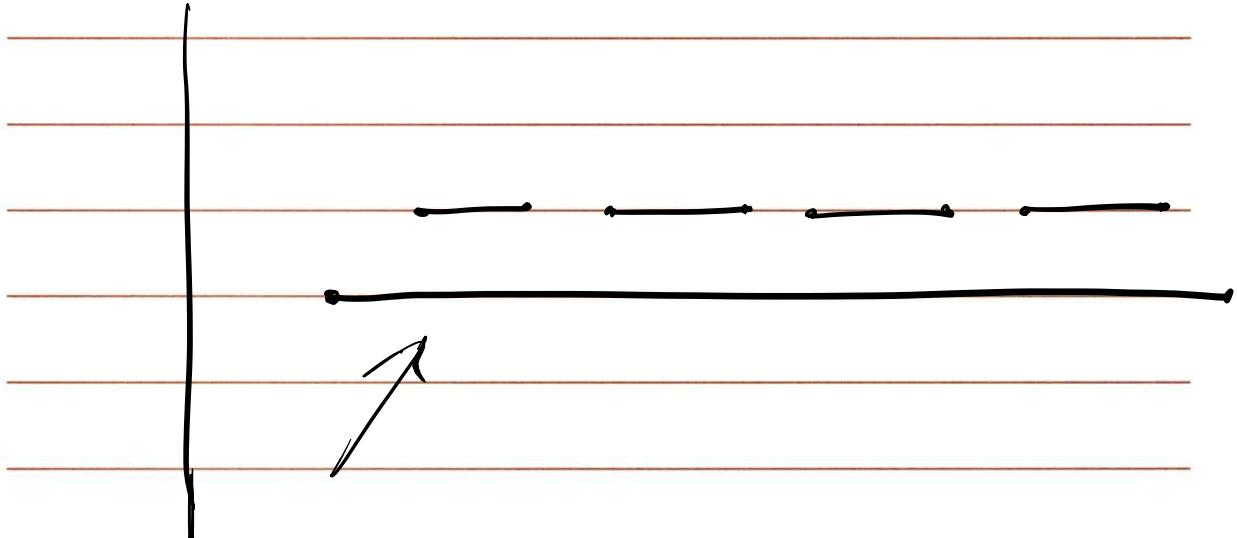

Input: Set of requests $\{1 \dots n\}$

i^{th} request starts at $s(i)$ and ends at $f(i)$

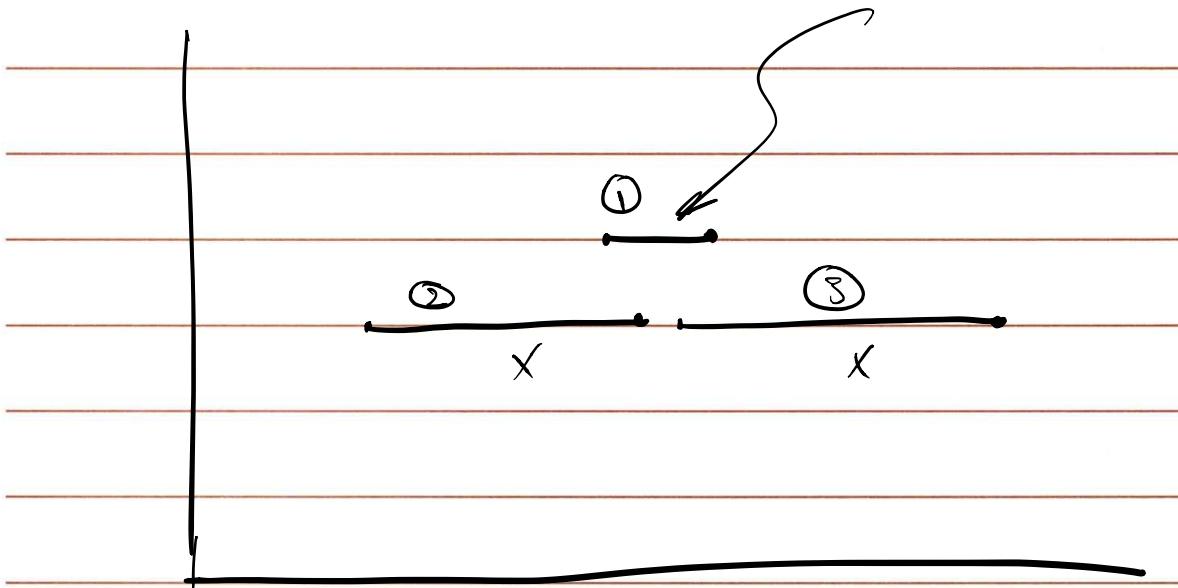

Objective: To find the largest compatible
subset of these requests

π

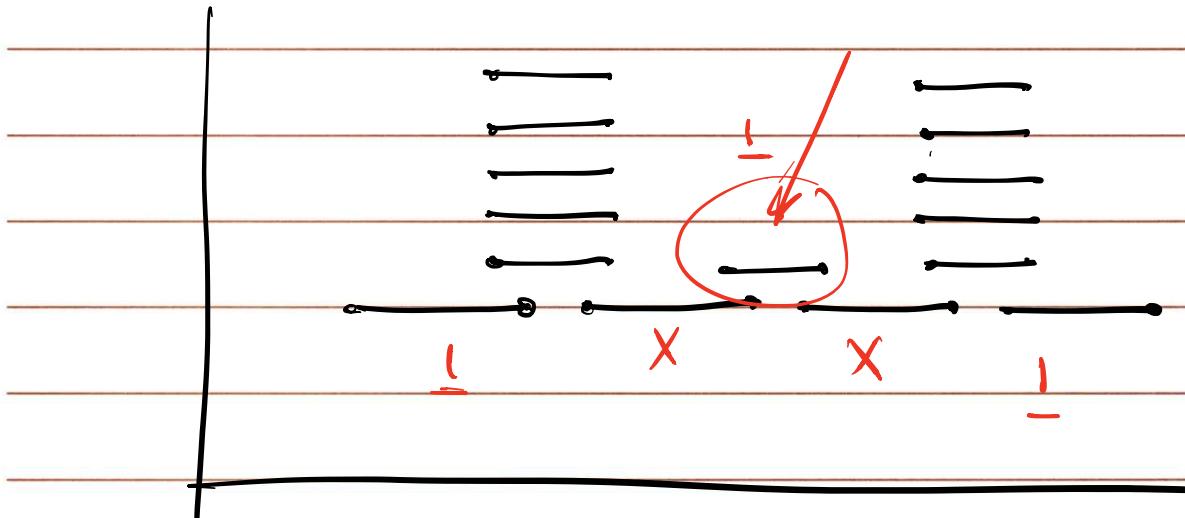

try#1 Earliest start time X

try#2 Smallest requests First X

try #3 Smallest no. of overlaps X

try #4 Earliest Finish Time

Solution:

Initially R is the complete set of requests
 $\& A$ is empty

While R is not empty

choose a request $i \in R$ that has the
smallest finish time

Add request i to A

(Delete all requests from R that
are not compatible w/ i)

end while

Return A

Proof of Correctness

- ① Show that A is a compatible set ←
- ② Show that A is an optimal set

Say A is of size k

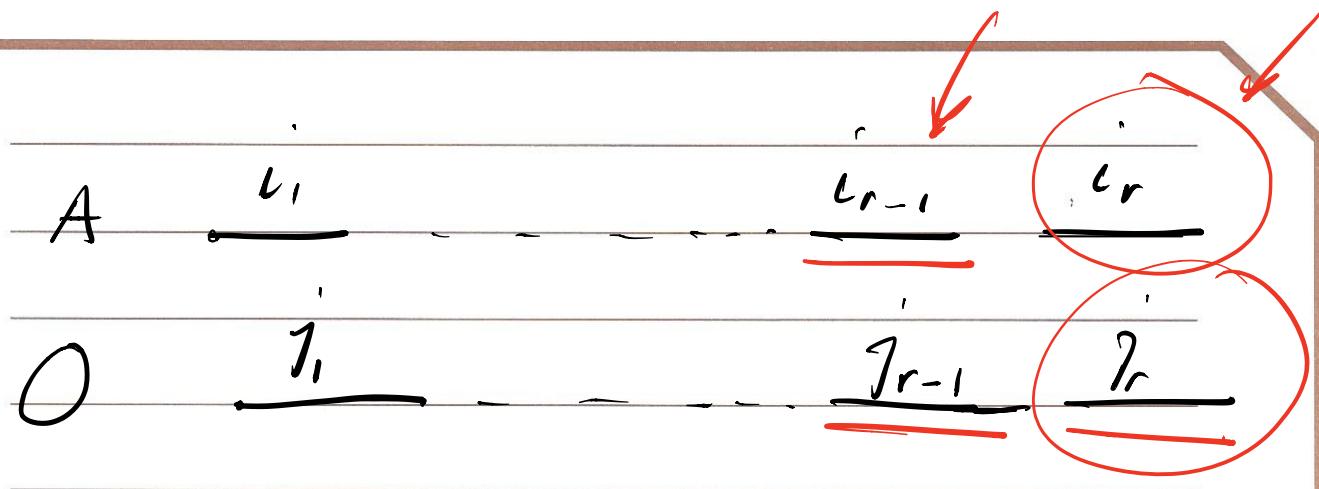

Say there is an opt. solution O

Show |A| = 10)

Requests in A: i_1, \dots, i_k

" " O: j_1, \dots, j_m

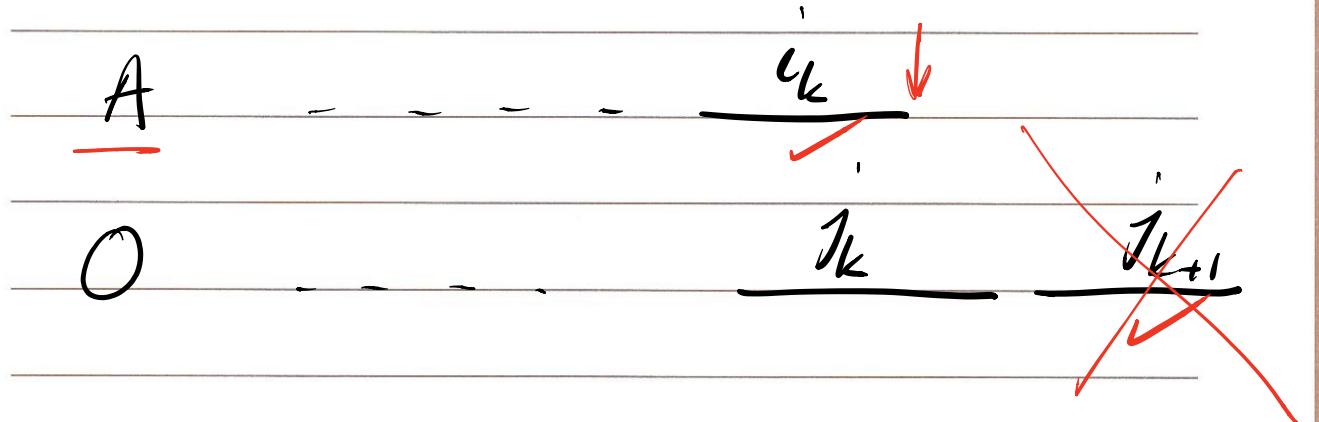

We will first prove that for all indices $r \leq k$, we have $f(i_r) \leq f(j_r)$

Base Case ✓

Induction step ✓

We can then easily prove that $|A| = |O|$

Implementation

$O(n \lg n)$

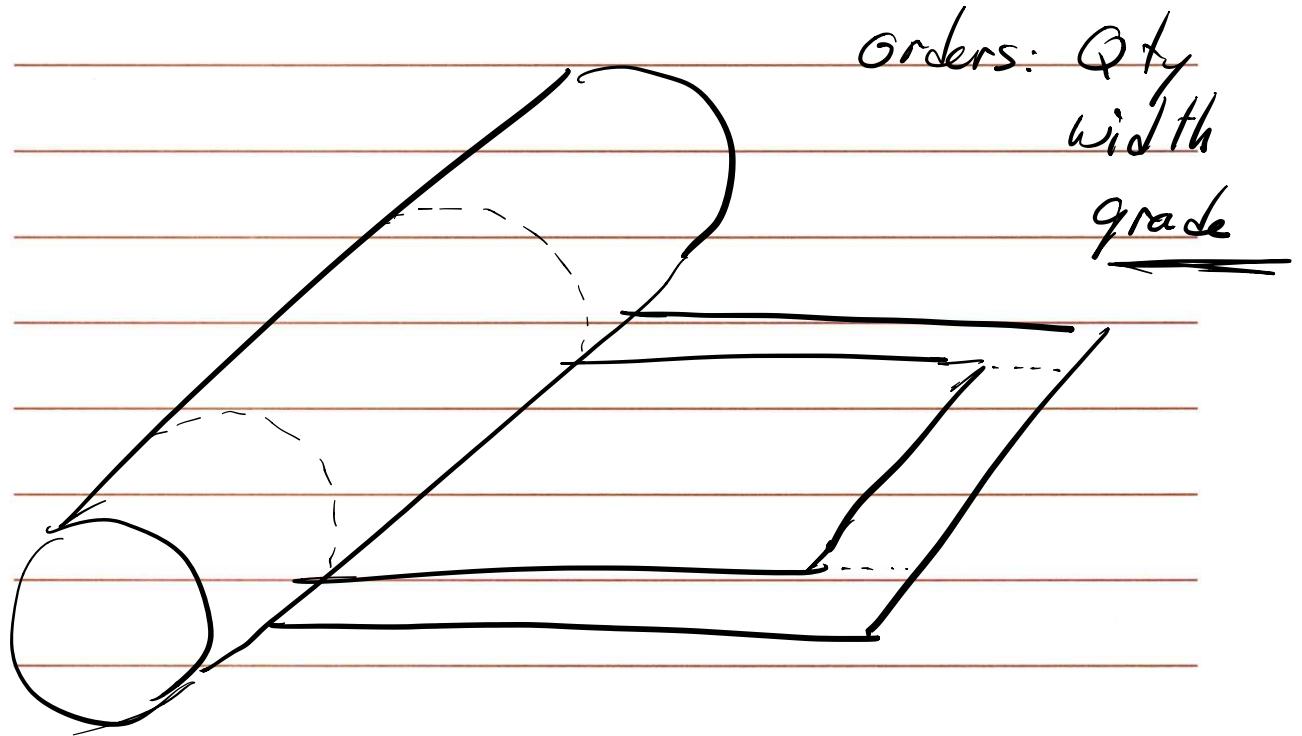

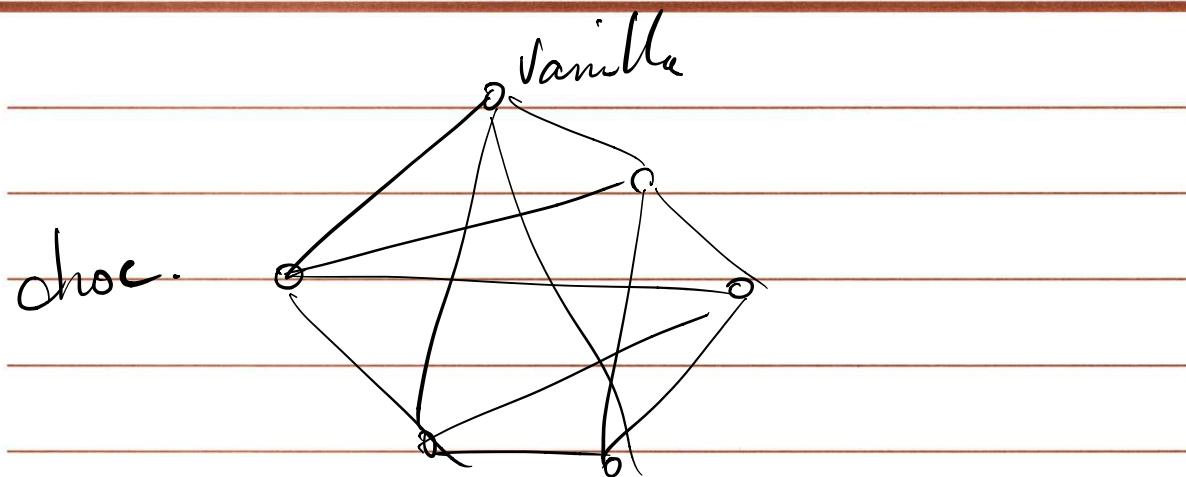

Sort requests in order of finish time
and label in this order:

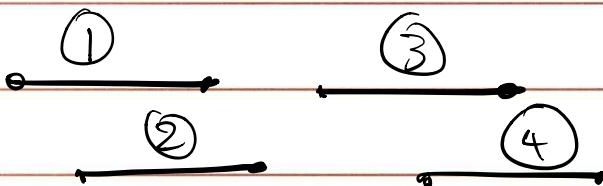

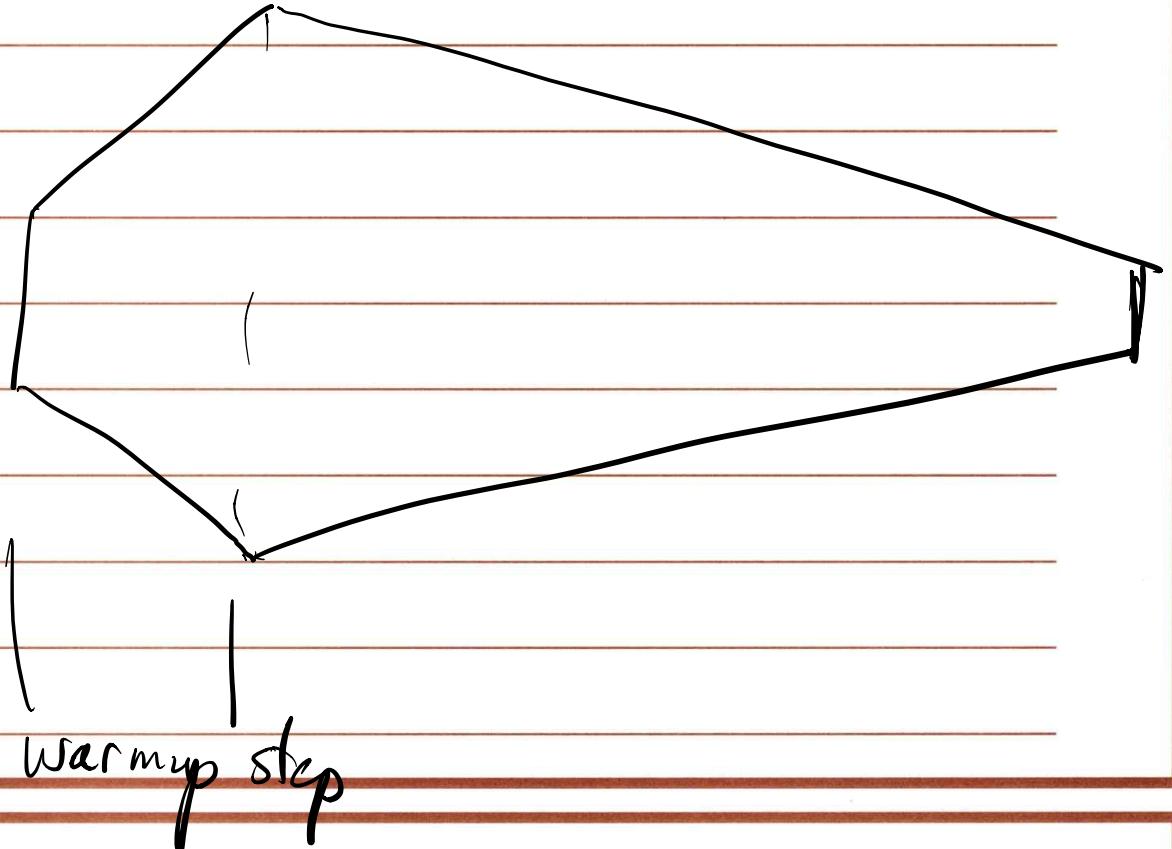

$$f(i) \leq f(j) \text{ where } i < j$$

Select requests in order of increasing $f(i)$, always selecting the first.
Then iterate through the intervals in this order until reaching the first interval for which $se(j) \geq f(i)$

overall Complexity is $O(n \lg n)$

ourso! A : $\{1, 3\}$

latest start time

an opt.-sol. : $\{2, 4\}$

$\{2, 4\}$

$\{1, 4\}$

Scheduling to Minimize
Lateness

Scheduling to Minimize Lateness

- Requests can be scheduled at any time

- Each request has a deadline

- Notation: $L_i = f(i) - d_i$

L_i is called 'lateness for request i '.

Goal: Minimize the Maximum Lateness $L = \max_i L_i$

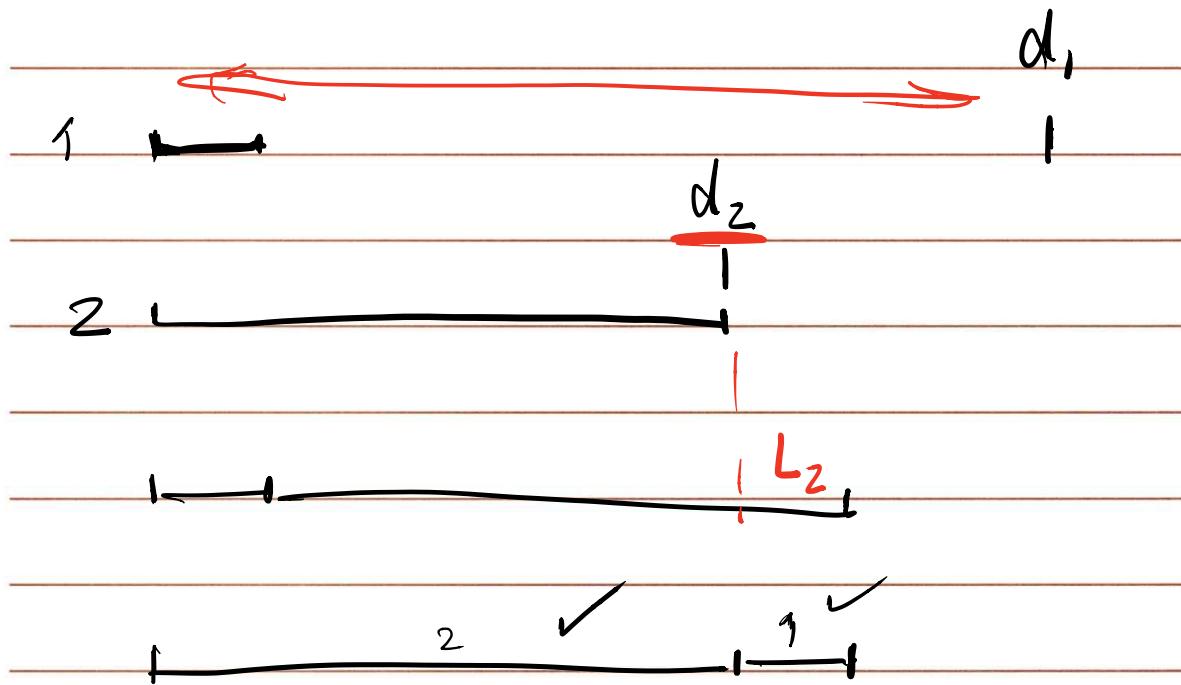

Sol. 1

job 1 late by 5 hrs
job 2 " 6 "

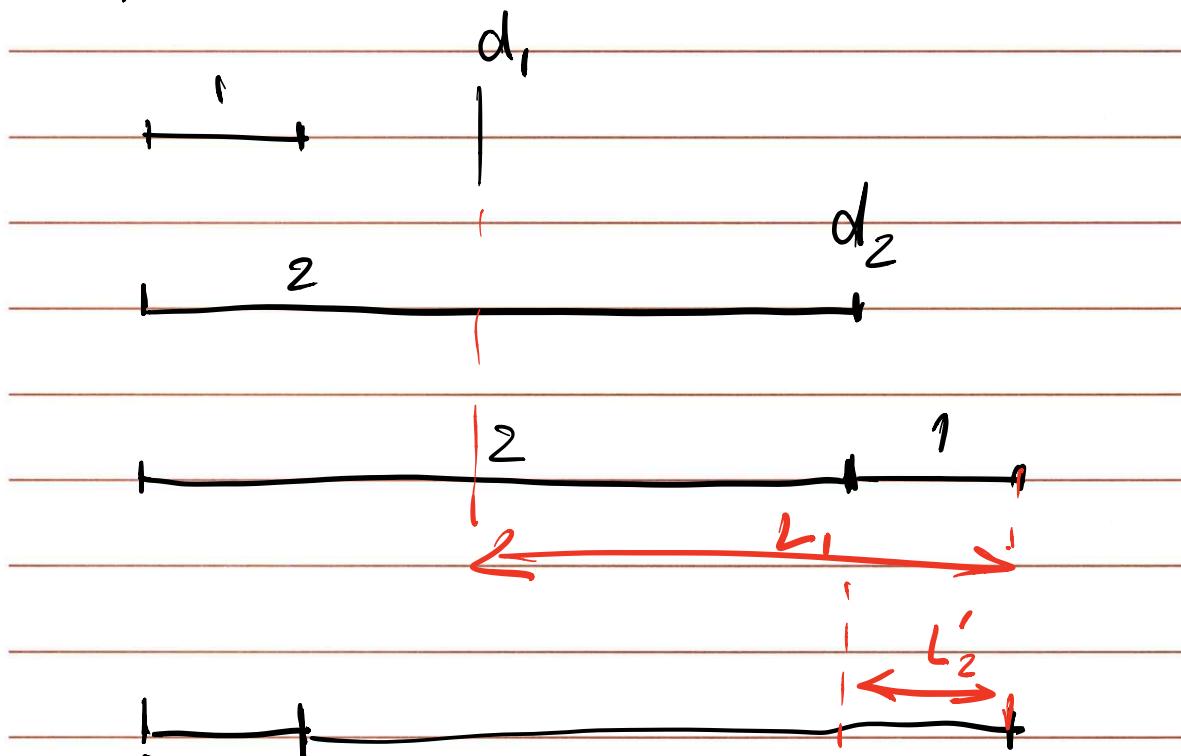

Sol. 2

job 1 late by 0 hrs
job 2 " 7 "

try #1 Shortest jobs First

try #2 Smallest slack time First

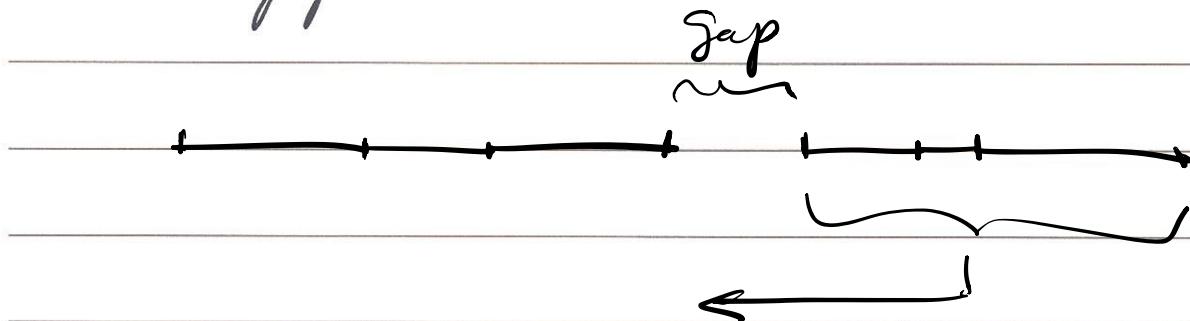

try #3 Earliest Deadline

Solution :

Schedule jobs in order of their deadline without any gaps between jobs.

Proof of Correctness

- ① There is an optimal solution with no gaps.

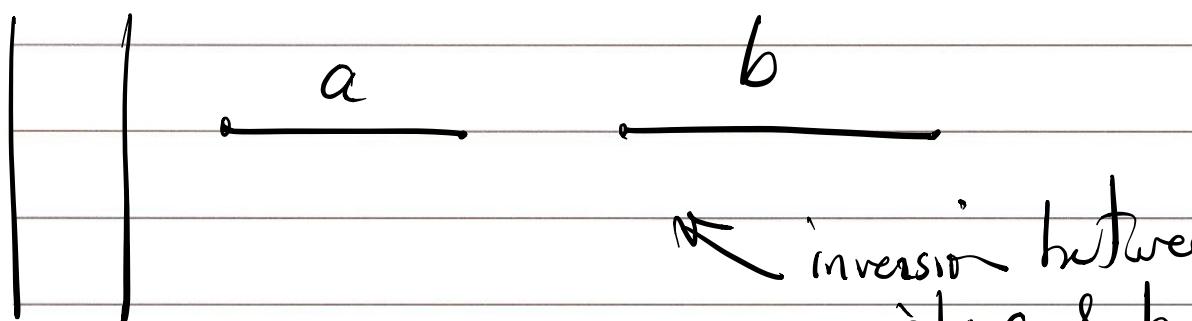

② Jobs with identical deadlines can be scheduled in any order without affecting Maximum Lateness.

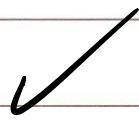

③ Def. Schedule A' has an inversion if a job i with deadline d_i is scheduled before job j with earlier deadline.

d_b d_a

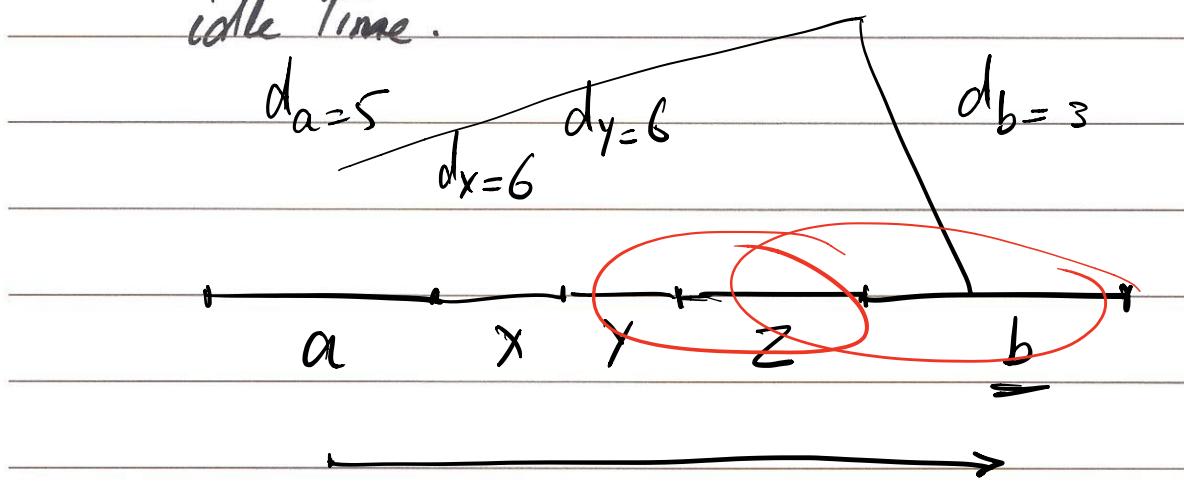

Observation: By def. A has no inversions.

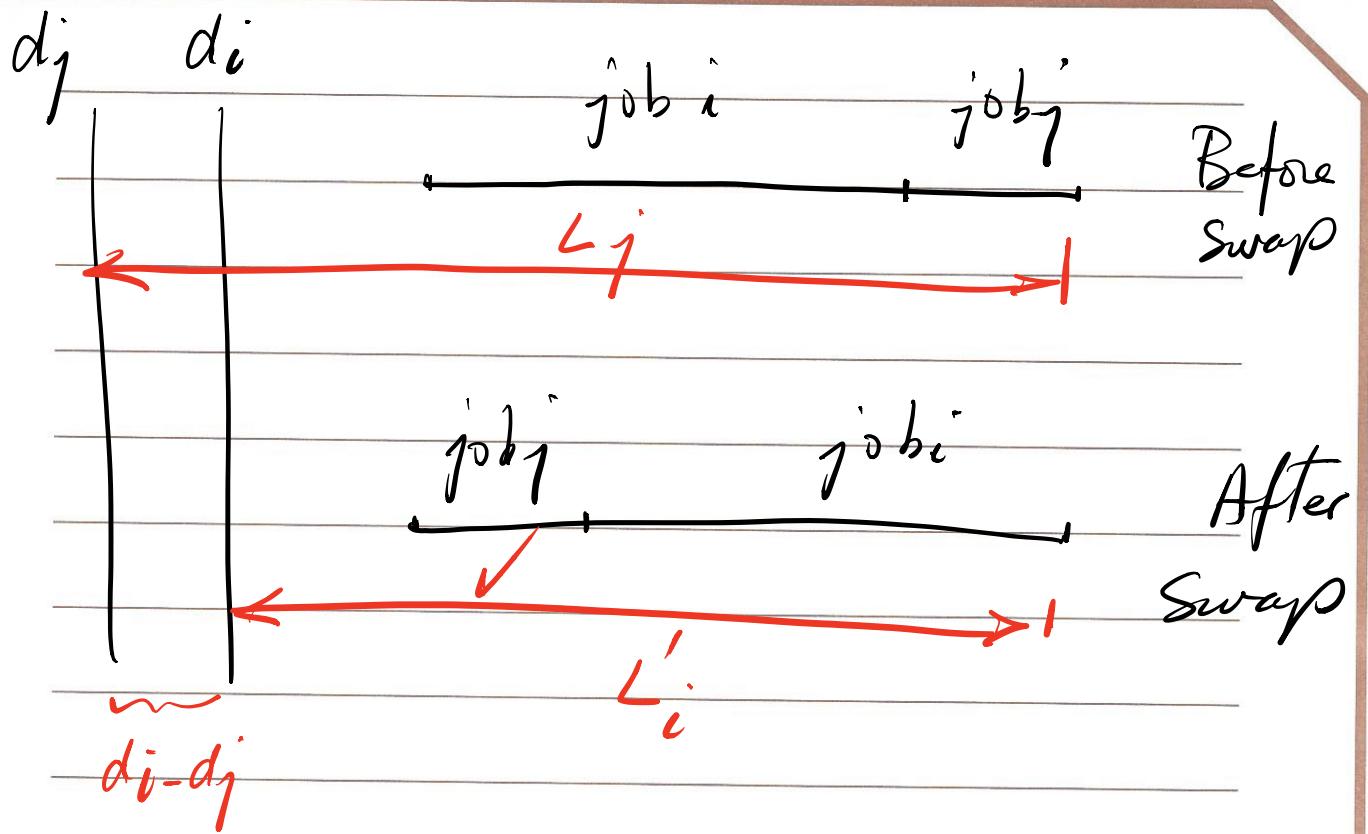

④ All schedules with no inversions and no idle time have the same Maximum Lateness.

= gap \geq

⑤ There is an optimal schedule that has no inversions and no idle time.

So, if there is an optimal solution that has inversions, we can eliminate the inversions one by one as shown above until there are no more inversions. This solution will also be optimal.

⑥ Proved that there exists an optimal schedule with no inversions and no idle time.

Also proved that all schedules with no inversions and no idle time have the same Maximum Lateness.

Our greedy algorithm produces one such solution \Rightarrow It will be optimal

Discussion 3

1. Let's consider a long, quiet country road with houses scattered very sparsely along it. We can picture the road as a long line segment, with an eastern endpoint and a western endpoint. Further, let's suppose that, despite the bucolic setting, the residents of all these houses are avid cell phone users. You want to place cell phone base stations at certain points along the road, so that every house is within four miles of one of the base stations.

Give an efficient algorithm that achieves this goal and uses as few base stations as possible.

Prove that your algorithm correctly minimizes the number of base stations.

2. Your friend is working as a camp counselor, and he is in charge of organizing activities for a set of campers. One of his plans is the following mini-triathlon exercise: each contestant must swim 20 laps of a pool, then bike 10 miles, then run 3 miles. The plan is to send the contestants out in a staggered fashion, via the following rule: the contestants must use the pool one at a time. In other words, first one contestant swims the 20 laps, gets out, and starts biking. As soon as this first person is out of the pool, a second contestant begins swimming the 20 laps; as soon as he or she is out and starts biking, a third contestant begins swimming, and so on.

Each contestant has a projected *swimming time*, a projected *biking time*, and a projected *running time*. Your friend wants to decide on a *schedule* for the triathlon: an order in which to sequence the starts of the contestants. Let's say that the *completion time* of a schedule is the earliest time at which all contestants will be finished with all three legs of the triathlon, assuming the time projections are accurate.

What is the best order for sending people out, if one wants the whole competition to be over as soon as possible? More precisely, give an efficient algorithm that produces a schedule whose completion time is as small as possible. Prove that your algorithm achieves this.

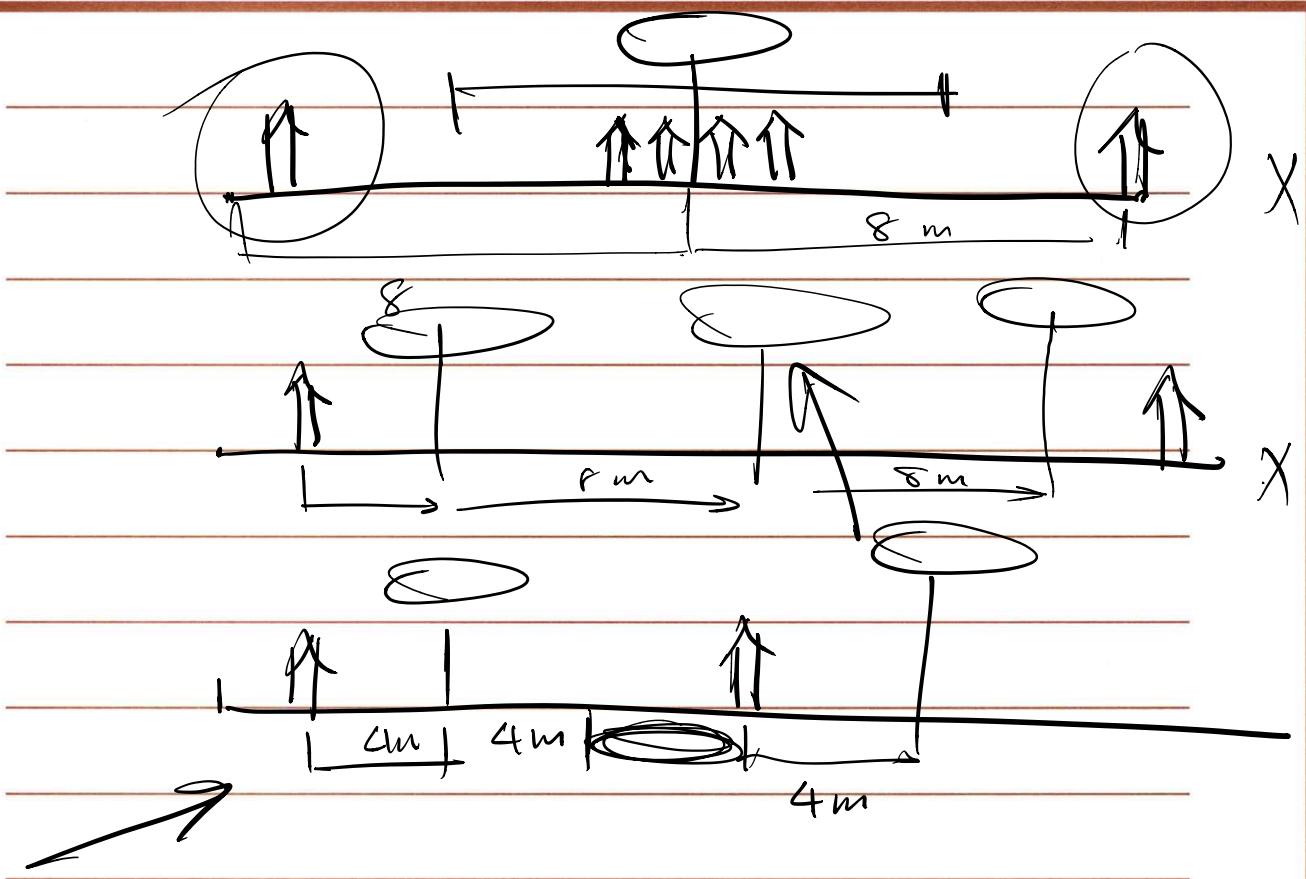

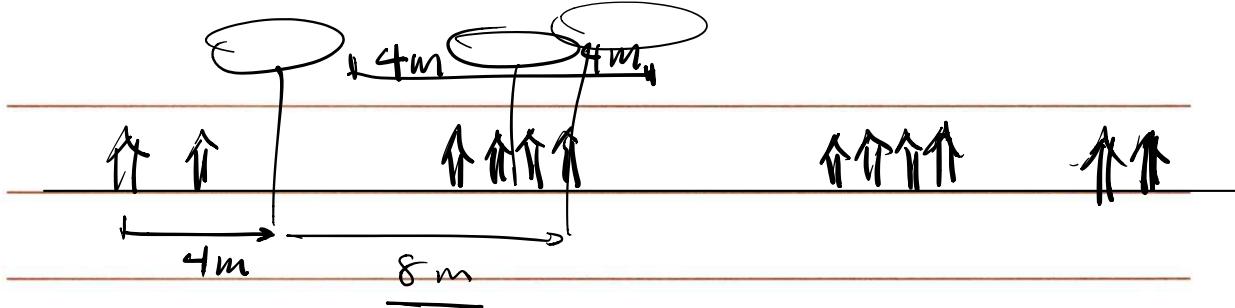

3. The values 1, 2, 3, . . . , 63 are all inserted (in any order) into an initially empty min-heap. What is the smallest number that could be a leaf node?

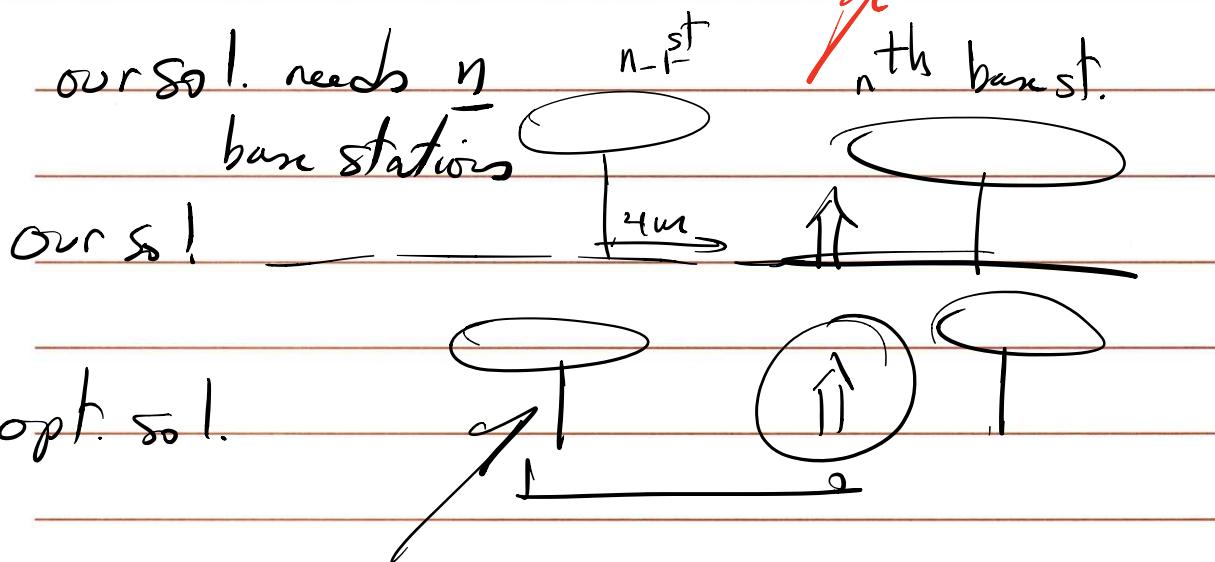

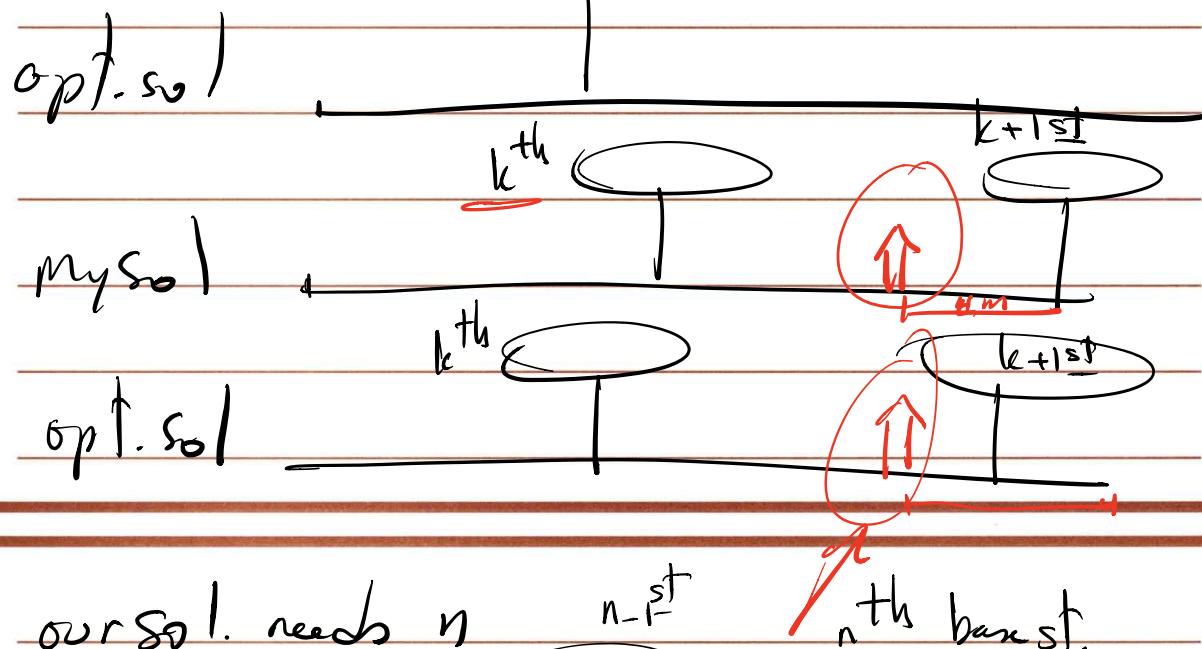

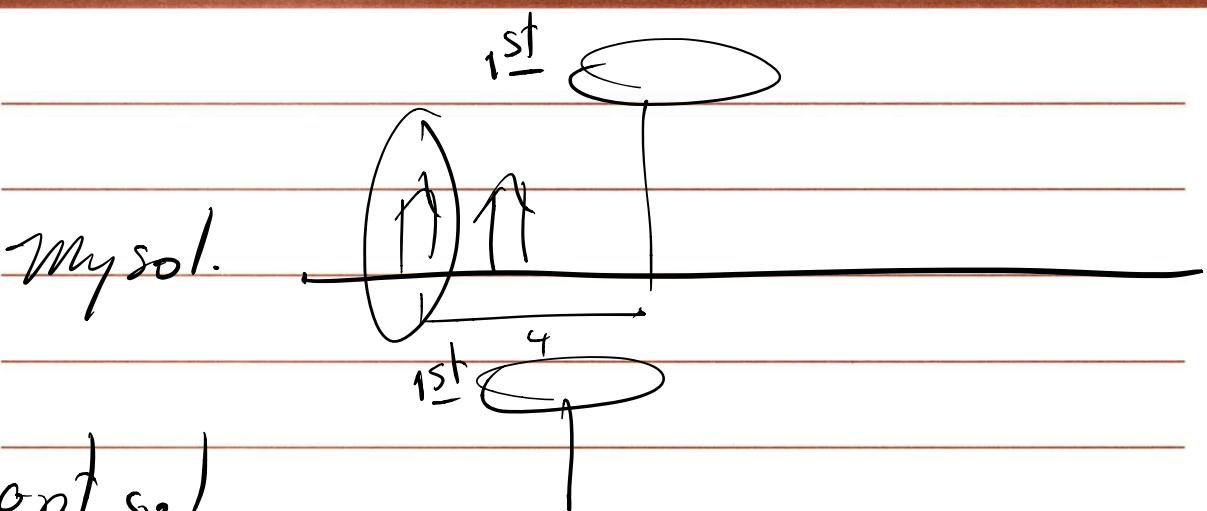

4. Given an unsorted array of size n . Devise a heap-based algorithm that finds the k -th largest element in the array. What is its runtime complexity?

5. Suppose you have two min-heaps, A and B, with a total of n elements between them. You want to discover if A and B have a key in common. Give a solution to this problem that takes time $O(n \log n)$ and explain why it is correct. Give a brief explanation for why your algorithm has the required running time. For this problem, do not use the fact that heaps are implemented as arrays; treat them as abstract data types.

Inversion: An athlete i with bike + run time $b_i + r_i$ is slower than athlete j with run + bike time $b_j + r_j$ and athlete j is scheduled first.

Discussion 3

1. Let's consider a long, quiet country road with houses scattered very sparsely along it. We can picture the road as a long line segment, with an eastern endpoint and a western endpoint. Further, let's suppose that, despite the bucolic setting, the residents of all these houses are avid cell phone users. You want to place cell phone base stations at certain points along the road, so that every house is within four miles of one of the base stations.

Give an efficient algorithm that achieves this goal and uses as few base stations as possible.

Prove that your algorithm correctly minimizes the number of base stations.

Solution:

Find the first house from the left (western most house) and go four miles to its right and place a base station there. Eliminate all houses covered by that station and repeat the process until all houses are covered.

Proof:

The proof is similar to that for the interval scheduling solution we did in lecture. We first show (using mathematical induction) that our base stations are always to the right of (or not to the left of) the corresponding base stations in any optimal solution. Using this fact, we can then easily show that our solution is optimal (using proof by contradiction).

- 1- Our base stations are always to the right of (or not to the left of) the corresponding base stations in any optimal solution:

Base case: we place our first base station as far to the right of the leftmost house as possible. If the base station in the optimal solution is to its right then the first house on the left will not be covered.

Inductive step: Assume our k th base station is to the right of the k th base station in the optimal solution. We can now show that our $k+1^{\text{st}}$ base station is also to the right of the $k+1^{\text{st}}$ base station in the optimal solution. To prove this we look at the leftmost house to the right of our k th base station which is not covered by our k th base station. We call this house H . If H is not covered by our k th base station, then it cannot be covered by the k th base station in the optimal solution since our base station is to the right of it. Our $k+1^{\text{st}}$ base station is placed 4 miles to the right of H . If the $k+1^{\text{st}}$ base station in the optimal solution is further to the right of our $k+1^{\text{st}}$ base station, then H is not going to be covered by either the k th base station nor the $k+1^{\text{st}}$ base station in the optimal solution so the $k+1^{\text{st}}$ base station in our solution must also be to the right of the $k+1^{\text{st}}$ base station in the optimal solution.

- 2- Now assume that our solution required n base stations and the optimal solution requires fewer base stations. We now look at our last based station. The reason we needed this base station in our solution was that there was a house to the right of our $n-1^{\text{st}}$ base station that was not covered by it. We call this house H . If H is not covered by our $n-1^{\text{st}}$

base station, then H will not be covered by the $n-1^{\text{st}}$ base station in the optimal solution either (since our base stations are always to the right of the corresponding base stations in the optimal solution). So, the optimal solution will also need another base station to cover H .

Complexity of our solution will be $O(n \log n)$ since we need to sort the houses first from left to right by their x coordinates. The actual positioning of the base stations will require $O(n)$ time.

2. Your friend is working as a camp counselor, and he is in charge of organizing activities for a set of campers. One of his plans is the following mini-triathlon exercise: each contestant must swim 20 laps of a pool, then bike 10 miles, then run 3 miles. The plan is to send the contestants out in a staggered fashion, via the following rule: the contestants must use the pool one at a time. In other words, first one contestant swims the 20 laps, gets out, and starts biking. As soon as this first person is out of the pool, a second contestant begins swimming the 20 laps; as soon as he or she is out and starts biking, a third contestant begins swimming, and so on.

Each contestant has a projected *swimming time*, a projected *biking time*, and a projected *running time*. Your friend wants to decide on a *schedule* for the triathlon: an order in which to sequence the starts of the contestants. Let's say that the *completion time* of a schedule is the earliest time at which all contestants will be finished with all three legs of the triathlon, assuming the time projections are accurate.

What is the best order for sending people out, if one wants the whole competition to be over as soon as possible? More precisely, give an efficient algorithm that produces a schedule whose completion time is as small as possible. Prove that your algorithm achieves this.

Solution:

Sort the athletes by decreasing biking + running time.

Proof:

The proof is similar to the proof we did for the scheduling problem to minimize maximum lateness. We first define an inversion as an athlete i with higher $(bi+ri)$ being scheduled after athlete j with lower $(bj+rj)$. We can then show that inversions can be removed without increasing the competition time. We then show that given an optimal solution with inversions, we can remove inversions one by one without affecting the optimality of the solution until the solution turns into our solution.

- 1- Inversions can be removed without increasing the competition time.

Remember that if there is an inversion between two items a and b , we can always find two adjacent items somewhere between a and b so that they have an inversion between them. Now we focus on two adjacent athletes (scheduled one after the other) who have an inversion between them, e.g. athlete i with higher $(bi+ri)$ is scheduled after athlete j with lower $(bj+rj)$. Now we show that scheduling athlete i before athlete j is not going push out the completion time of the two athletes i and j . We do this one athlete at a time:

- By moving athlete i to the left (starting earlier) we cannot increase the completion time of athlete i
- By moving athlete j to the right (starting after athlete i) we will push out the completion time of athlete j but since the swimming portion is sequential and athlete j gets out of the pool at the same time that athlete i was getting out of the pool before removing the inversion, and since athlete j is faster than athlete i in the biking and running sections, then the completion time for athlete j will not be worse than the completion time for athlete i prior to removing the inversion.

- 2- Since we know that removing inversions will not affect the completion time negatively, if we are given an optimal solution that has any inversions in it, we can remove these inversions one by one without affecting the optimality of the solution. When there are no more inversions, this solution will be the same as ours, i.e. athletes sorted in descending order of biking+running time. So our solution is also optimal.
